Project: Acoustic Modem

1 Introduction

In this project, you are going to implement the receiver for an acoustic modem. An acoustic modem is a device which sends digital signals using sound waves. This approach was used for internet access for many years.

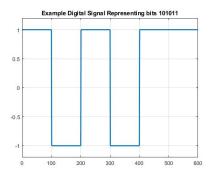

Nowadays it is still the method of communication of choice for underwater communications because acoustic signals propagate better than electromagnetic signals in salt water.

The goal is for you to decode a message contained in an acoustic signal.

2 The approach

The basic idea here is to use amplitude modulation to transmit signals through the acoustic channel.

Digital information can be transmitted using a sequence of pulses, with positive pulses representing ones and negative pulses representing zeros. E.g. a continuous-time (CT) waveform m(t) as shown can be used to represent a bit sequence '101011';

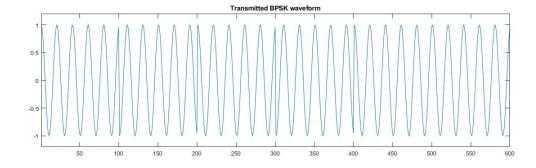

In this example, a pulse of width 100 time units is used. The time between the pulses is known as the Symbol Period.

This signal cannot be transmitted through the air. It will have to be translated to higher frequencies by multiplying with a high-frequency cosine. This is the same approach used in Amplitude Modulation that you saw earlier in the semester.

Suppose the boxy message signal is m(t), then the transmitted signal is

$$x(t) = m(t)\cos(2\pi f_c t) \tag{1}$$

where f_c is known as the carrier frequency. The x(t) signal would look something like the following:

Project: Acoustic Modem

This type of data modulation is called binary-phase-shift keyeing, because the information is carried in the phase of the cosine, and binary because there are one of 2 possible phase offsets to the cosine. Each transition from a 0 to a 1 and vice-versa results in a phase shift of the cosine.

Note that in practice, the frequency of the cosine should be considerably higher than what's illustrated in the graph, but we used a lower frequency cosine so the graph is easier to read.

The waveform x(t) is what should be transmitted from the speaker of an acoustic modem.

At the receiver end, the received signal y(t) is multiplied by a cosine and low-pass filtered, to produce an approximation to m(t), which can be used to decode the transmitted bits. Please refer to Homework 2 for how Amplitude Modulation (AM) works.

3 What you need to do

3.1 Minimum Viable Product

We have provided the following files

- modem_tx.m script to generate a transmit signal vector and store it into a .wav file
- modem_rx_starter.m starter script to build your receiver
- short_modem_rx.mat and long_modem_rx.mat two files which contain received samples of a short and long transmission of data.
- find_start_of_signal.m function used to detect when the signal is present in the received data

Your job is to decode the messages contained in the two .mat files. Start with the short file. The message in it is "Hello". The transmit code is given to you for reference in modem_.m

3.2 Possible directions for further exploration

- 1. Generate new data and transmit it over the air. Please see section on practical considerations below.
- 2. Reduce the symbol period. The symbol period directly impacts how quickly your data is transmitted. The smaller you can make it, the higher your data rate. (Note that you will have to do the previous part first).
- 3. Transmit Quadrature signals. You can transmit two independent bit-streams through the channel, one modulated by cosine and another modulated by sine and have the signals added together. To decode, you simply multiply by the corresponding sine/cosine signal.
- 4. Use multi-level pulses.
- 5. Transmit very long sequences of data. This will be challenging as the clocks on the mobile phone and the computer will go out of sync after some time, and you will have to implement a phase-locked loop in software to digitally correct for the drift in the clocks. Believe it or not, one of the ways to correct for the drift is a PID loop like what you saw in the first half of the semester! The basic idea is that you are trying to drive a phase error (i.e. an angle) to zero. Something that you all did in a different context a couple of months ago! Note that this will be challenging given the short time we have. Please talk to Siddhartan if you want to try this.

4 Practical Considerations

4.1 Lining up the signals

The data in the .mat files was collected as follows:

- 1. modem_tx was run
- 2. the resulting .wav file was transferred to a mobile phone
- 3. A recorder object was created in MATLAB and recording was started. You can see MATLAB documentation on how this is done.

Project: Acoustic Modem

- 4. The .wav file was played on the mobile phone about 2 feet away from the laptop which was recording on MATLAB
- 5. The recorded data was stored in the vector y_r.

Since the receiver was started first (this is done to ensure that we don't miss the start of the transmission), the signal lives somewhere in the middle of y_r. You can plot y_r to see this. So we need to truncate it to start at the correct point. The standard way to do this is to prepend a known, but noise-like signal before the actual data bearing signal. Then an operation called cross correlation can be done to determine the start of the signal. We have already done this for you in the modem_tx.m and modem_rx_starter.m files, so you don't need to worry about this part.

4.2 Flipping signals

Due to propagation through the channel between the speaker on the phone and the mic on the computer, there is a good chance that the signal could arrive with its sign flipped at the receiver. You could flip it by hand or implement some automatic way to check if a sign flip is necessary. Note that in the two data files we provided for you, it is not necessary to flip the sign. You will only need to do this if you choose to make your own transmissions.

5 Deliverables

- 1. A brief report with introduction, block diagram, equations used, graphs of signals in the time domain, and graphs of signals in the frequency domain.
- 2. Link to audio recordings if you produced new ones.
- 3. Code listing
- 4. Optional demo in class on Friday, 5/8/2020.
